# Como deixar a sua aplicação até 20x mais lenta com FastAPI

Júlio César Batista

### Como começou

Mar 22, 3:54pm - Mar 22, 4:00pm

•••

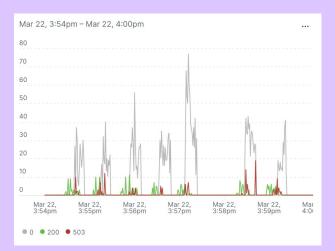

Response Code	Count
0	2.67 k
200	241
503	149

### Como está indo

Apr 22, 12:56pm - Apr 22, 1:01pm

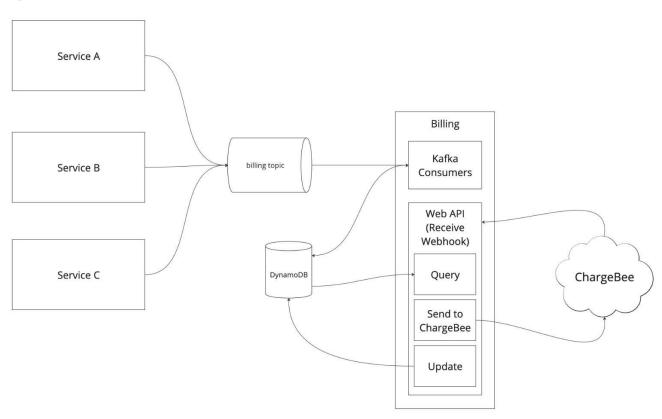

...

Response Code	Count
200	48 k

## Visão geral

## Configuração dos testes

#### Sem dependência do Chargebee

Conseguir o mesmo nível de concorrência, restrições de rede (timeouts) e execução de código (acessar DyanmoDB, enviar para o Chargebee, atualizar o Dynamo)

### Cuidado com os recursos do sistema

Pode ter que aumentar os file handlers ulimit -n

#### Script

Usando aiohttp e multiprocessing

# Resultado inicial para 1k requisições

30%

Erro

- Sem resposta / timeout

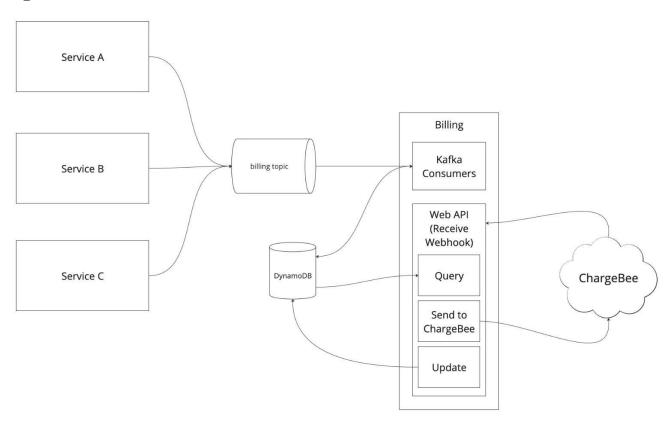

70%

- HTTP 503

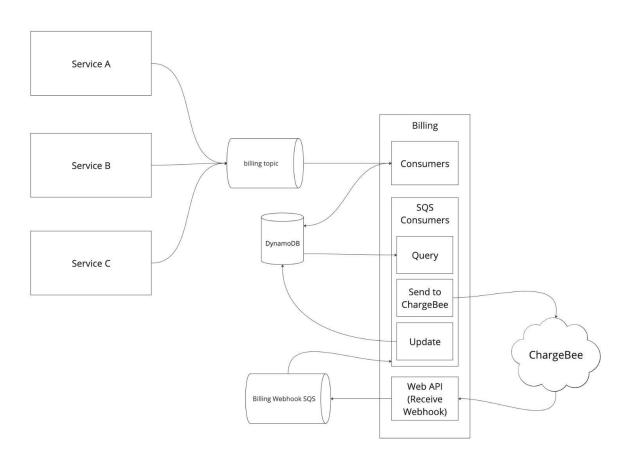

Sucesso

- HTTP 200

## O que podemos melhorar?

## Adicione uma fila

### 1k requisições com SQS

45%

55%

Erro

- Sem resposta / timeout

- HTTP 503

Sucesso

- HTTP 200

50%

de melhora na taxa de sucesso

# Controle sobre a capacidade de processamento

### Controle sobre o poder de processamento

Se queremos aumentar/diminuir o nosso poder de processamento, só precisamos adicionar/remover consumidores.

#### Processar mais requisições

Como o processamento de requisições envolve apenas adicionar em uma fila, se precisarmos de mais poder de processamento podemos adicionar mais pods sem restrições.

### Sem problemas com HTTP 429 (rate limit)

O processamento de requisições não está mais limitado pela quantidade de requisições que podemos enviar para o Chargebee ou pelo tempo de resposta deles.

## Uma vez que melhoramos a arquitetura do serviço, o que podemos fazer?

- Usar uvloop
- Usar httptools
- Usar async handlers
- Aumentar thread pool
- Evitar validação duplicada de JSON
- Usar ORJSONResponse
- Desabilitar logs do uvicorn com --no-access-log
- Usar ASGIMiddleware ao invés de BaseHTTPMiddleware

## 1k requisições com uvloop + httptools

- Nosso projeto base já usa uvicorn[standard] que inclui uvloop e httptools se possível
  - https://www.uvicorn.org/#guickstart
- Esse foi um teste de verificação com uvicorn sem os extras

38%

Sucesso - HTTP 200 62%

#### Erro

- Sem resposta / timeout
- HTTP 503

#### Antes de continuar

### Um pouco sobre uvicorn

#### Uvicorn + FastAPI

uvicorn é o servidor que usamos para rodar FastAPI. Verifique as <u>configurações aqui</u>

#### Limite a concorrêncua

--limit-concurrency <int>
Quantas requisições
concorrentes o seu servidor
consegue processar? Por
padrão, até esgotar os recursos
do sistema.

#### Fila de requisições

--backlog <int>
Quantas requisições são
mantidas na accept queue antes
de retornar 503 para novas
requisições?
Por padrão, 2048.

# Configuração dos tests [atualizada]

#### Apenas adiciona uma mensagem no SQS

Não é mais necessário simular todo o processo de acessar o DynamoDB e Chargebee, apenas adicionamos uma mensagem em uma fila.

#### Sem necessidade de dados reais

Como apenas adicionamos uma mensagem no SQS, não importa mais se os IDs existem e se existem dados para processar.

#### O objetivo é o servidor web

Nós queremos melhorar o desempenho do servidor web, não necessariamente a capacidade de retornar dados para o Chargebee.

#### Usar uma ferramenta padrão

Existem muitas <u>opções</u>. Usamos <u>vegeta</u>.

# 59% 932ms 42rps

Uma espiada no código

## O que tem de errado aqui?

```
@router.post(PENDING_INVOICE_CREATED_PATH)
async def pending_invoice_created_webhook_handler(
    request: Request,
    producer: Producer = Depends(Producer),
) -> JSONResponse:
    body = await request.body()
    body_str = body.decode("utf-8")
    try:
        PendingInvoiceCreated.model_validate_json(body_str)
        producer.send_message(body_str)
    except ValidationError as e:
        pass
    except Exception as e:
        pass
    return JSONResponse(status_code=200, content={...})
```

## Como FastAPI lida com concorrência?

#### **Threading**

A forma mais comum para lidar com concorrência é usar threads.

#### A GIL

Python a famosa GIL que limita a capacidade de processamento concorrente.

#### **CPU ou IO**

O problema da GIL é "apenas" para tarefas que exigem CPU, para tarefas com IO, é ok usar threads.

#### async não é thread

Funções async não são threads. Existe apenas a thread principal e um gerenciador de eventos (event loop)coordenando tarefas cooperativas, não preemptivas (OS threads).

## Como FastAPI lida com concorrência?

#### async handlers

Rodam na thread principal e não devem ser bloqueantes, caso contrário a thread para por completo e o servidor para de processar requisições.

#### sync handlers

Rodam em um thread pool. Podem bloquear, mas se o pool estiver cheio a thread principal será bloqueada até que um espaço seja liberado.

#### Injeção de dependência

As mesmas regras se aplicam para a injeção de dependências (Depends (some function)).

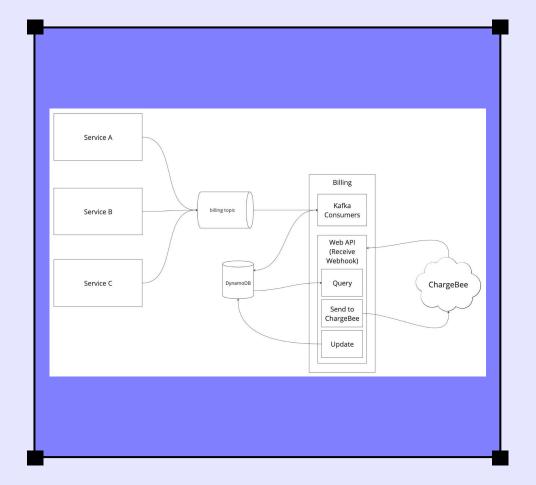

## Uma *blocking call* em um *async handler*

- A chamada do SQS é bloqueante (network IO)
- Como é um async handler, está rodando na thread principal
- Durante a chamada bloqueante, o handler não devolve o controle para o event loop
- A thread principal fica incapacitada de processar/aceitar novas requisições até que o SQS retorne

```
@router.post(PENDING_INVOICE_CREATED_PATH)
async def pending_invoice_created_webhook_handler(
    request: Request,
    producer: Producer = Depends(Producer),
) -> JSONResponse:
    body = await request.body()
    body_str = body.decode("utf-8")
    try:
        PendingInvoiceCreated.model_validate_json(body_str)
        producer.send_message(body_str)
    except ValidationError as e:
        pass
    except Exception as e:
        pass
    return JSONResponse(status_code=200, content={...})
```

# Multiplos bloqueios no async handler

 Não era apenas sobre mover para o SQS, mas remover multiplas blocking calls em um async handler

#### **Execute no threadpool**

# Mover as blocking calls para o threadpool

FastAPI possui run\_in\_threadpoolque
 executa funções no mesmo threadpool dos sync
 handlers

```
from fastapi.concurrency import run in threadpool
@router.post(PENDING INVOICE CREATED PATH)
async def pending invoice created webhook handler(
  request: Request,
  producer: Producer = Depends(Producer),
) -> JSONResponse:
  body = await request.body()
  body str = body.decode("utf-8")
  try:
      PendingInvoiceCreated.model validate json(body str)
       await run in threadpool (producer.send message,
body str)
  except ValidationError as e:
       pass
   except Exception as e:
       pass
  return JSONResponse(status code=200, content={...})
```

#### vegeta attack -rate 200 -duration 4m (sustentar 200 RPS) - Total de 48k requisições em 4 minutos

Apr 22, 12:56pm - Apr 22, 1:01pm

## "Uma pessoa que nunca cometeu um erro nunca tentou algo novo"

- Albert Einstein

#### Suposições

Às vezes nossas suposições nos confundem, como assumir que requisições eram processadas em threads.

### Fique de olho ao trabalhar com async

Async é legal, mas requer atenção extra para não bloquear o event loop e travar a aplicação, algo que não ocorre com threads.

#### 200 rps

Cada requisição usa ~5ms do tempo de CPU. É possível que possamos otimizar ainda mais.

Apêndice

# 200 RPS é bom?

# O que podemos esperar?

FastAPI diz que pode processar milhares de RPS

Veja benchmarks.

Qual a configuração para processar tantas requisições?

Qual o hardware? Precisa de multiplos workers?

Como isso se compara com a nossa infra?

Benchmarks podem mudar em comparação com a nossa infra e como isso afeta o throughput?

Recursos (kubernetes)

Requests 0.25 CPU and 256Mi RAM. Limits 512Mi RAM, sem limite para CPU.

200 worker threads
